THREE CHIPS ARE BETTER THAN ONE.
Our competitors always use three chips in their best and most expensive projectors. At JVC, we use three D-ILA chips in ALL of our projectors; giving them superior color reproduction, better gradation and smoother images over their single-chip counterparts—at a competitive cost.

Why are three chips better than one? Lower-cost single-chip models rapidly project the picture one color at a time and rely on the viewer's eyes to blend alternating flashes of red, green and blue images into the desired colors. Three-chip projectors simultaneously produce images on separate RGB panels inside the projector and then combine the light beams, projecting a full color image on the screen. The simple fact is that three chips produce better, more stable images, free of flicker and annoying "rainbow" effects. JVC three-chip D-ILA projectors provide a more natural, comfortable viewing experience—silky smooth images full of rich colors.

D-ILA projectors offer higher resolution by packing more pixels onto each chip. Unlike our competitors, the tiny space between pixels on the D-ILA chip is not black, and there are no hinges or non-reflective areas in the pixel itself. D-ILA projected images are free of any visible pixel grid.

JVC's exclusive AG circuitry provides better gradations for a more lifelike look. At any level of brightness, D-ILA images have a richer, more colorful look than their single-chip counterparts.

With D-ILA three-chip projectors, you'll be amazed by the smooth, stunning and color-rich images. Once you see the D-ILA difference, you'll never accept anything less.
